Department of Systems Engineering and Engineering Management, The Chinese University of Hong Kong, Shatin, Hong Kong {ywhuang@se.cuhk.edu.hk, zhang@se.cuhk.edu.hk}

This paper studies the possibilities of the linear matrix inequality characterization of the matrix cones formed by nonnegative complex Hermitian quadratic functions over specific domains in the complex space. In its real-case analog, such studies were conducted in Sturm and Zhang [Sturm, J. F., S. Zhang. 2003. On cones of nonnegative quadratic functions. Math. Oper. Res. 28 246–267]. In this paper it is shown that stronger results can be obtained for the complex Hermitian case. In particular, we show that the matrix rank-one decomposition result of Sturm and Zhang [Sturm, J. F., S. Zhang. 2003. On cones of nonnegative quadratic functions. Math. Oper. Res. 28 246–267] can be strengthened for the complex Hermitian matrices. As a consequence, it is possible to characterize several new matrix co-positive cones (over specific domains) by means of linear matrix inequality. As examples of the potential application of the new rank-one decomposition result, we present an upper bound on the lowest rank among all the optimal solutions for a standard complex semidefinite programming (SDP) problem, and offer alternative proofs for a result of Hausdorff [Hausdorff, F. 1919. Der Wertvorrat einer Bilinearform. Mathematische Zeitschrift 3 314–316] and a result of Brickman [Brickman, L. 1961. On the field of values of a matrix. Proc. Amer. Math. Soc. 12 61–66] on the joint numerical range.

Key words: matrix rank-one decomposition; complex co-positivity cone; quadratic optimization; S-procedure

1. Introduction. The aim of this paper is to extend the results on the cone of nonnegative quadratic functions, studied by Sturm and Zhang in [9], from the real-valued to the complex domains. Sturm and Zhang [9] developed a matrix rank-one decomposition technique, which is a key technique in their approach to establish the linear matrix inequality representability of a class of matrix cones of nonnegative quadratic functions. It turns out that in the case of complex (Hermitian) quadratic forms, the rank-one decomposition result can actually be improved. In particular, we show in this paper that it is possible to find a rank-one decomposition for a positive semidefinite Hermitian matrix such that the inner-product between any of the rank-one matrices and two prescribed Hermitian matrices are constant, respectively. As a comparison, in the real case, the inner-product of these rank-one matrices and only one prescribed matrix can be made constant in general.

The organization of this paper is as follows. Section 2 studies such matrix rank-one decompositions, and §3 is devoted to the description of the cone of nonnegative complex quadratic functions. The results of Sturm and Zhang [9] can be applied to solve quadratic optimization problems, as shown in Ye and Zhang [11]. Some of the results can be strengthened for the Hermitian forms, due to the results established in §§2 and 3. Section 4 is devoted to the complex quadratic programming problem. In §§5, we study the rank of optimal solutions for a standard complex SDP, in light of the new rank-one decomposition result. Finally, in §6 we investigate some interesting relationships between the rank-one decomposition theorem and the joint numerical range.

Notation. Throughout, we denote by $\bar{a}$ the conjugate of a complex number $a$, and by $\mathbb{C}^n$ the space of $n$-dimensional complex vectors. For a given vector $z \in \mathbb{C}^n$, $z^H$ denotes the conjugate transpose of $z$. The space of $n \times n$ real symmetric and complex Hermitian matrices are denoted by $\mathcal{S}^n$ and $\mathcal{H}^n$, respectively. For a matrix $Z \in \mathbb{H}^n$, we write $\text{Re} Z$ and $\text{Im} Z$ for the real and imaginary parts of $Z$, respectively. Matrix $Z$ being Hermitian implies that $\text{Re} Z$ is symmetric and $\text{Im} Z$ is skew-symmetric. We denote by $\mathcal{S}^n_+ (\mathcal{S}^n_{++})$ and $\mathcal{H}^n_+ (\mathcal{H}^n_{++})$ the cones of real symmetric positive semidefinite (positive definite) and complex Hermitian positive semidefinite (positive definite) matrices, respectively. The notation $Z \succeq_+ (\succ_+)$ means that $Z$ is positive semidefinite (positive definite).

For two complex matrices $Y$ and $Z$, their inner product $Y \bullet Z = \text{Re} (\text{tr} Y^H Z) = \text{tr} [(\text{Re} Y)^T (\text{Re} Z) + (\text{Im} Y)^T (\text{Im} Z)]$, where $\text{tr}$ denotes the trace of a matrix and $^T$ denotes the transpose of a matrix. For a square matrix $M$, $\text{diag}(M)$ stands for a column vector whose elements are diagonal components of $M$.

2. A rank-one decomposition of Hermitian positive semidefinite (PSD) matrices. Let $X \in \mathcal{S}^n$ be a real symmetric positive semidefinite matrix, and $A \in \mathcal{S}^n$ be a real symmetric matrix. It follows by Sturm and Zhang [9] that there is a rank-one decomposition of $X$:

$$X = \sum_{j=1}^r x_j x_j^T \quad \text{such that} \quad x_j^T A x_j = \frac{A^T X}{r}, \quad \text{for } j = 1, \ldots, r,$$

where $r = \text{rank} X$. 

758
Now we shall show that in the Hermitian case the decomposition result can be extended to two matrices.

**Theorem 2.1.** Suppose that \( Z \in \mathcal{C}^n \) is a complex Hermitian positive semidefinite matrix of rank \( r \), and \( A, B \in \mathcal{C}^n \) be two given Hermitian matrices. Then, there is a rank-one decomposition of \( Z \),

\[
Z = \sum_{j=1}^{r} z_j z_j^H,
\]

such that

\[
z_j^H A z_j = \frac{A \cdot Z}{r}, \quad z_j^H B z_j = \frac{B \cdot Z}{r}, \quad j = 1, \ldots, r.
\]

**Proof.** It follows from Sturm and Zhang [9, Corollary 4] that there is a decomposition of \( Z \)

\[
Z = \sum_{j=1}^{r} u_j u_j^H \quad \text{such that} \quad u_j^H A u_j = \frac{A \cdot Z}{r}, \quad \text{for} \quad j = 1, \ldots, r.
\]

If \( u_j^H B u_j = B \cdot Z/r \) for any \( j = 1, \ldots, r \), then we are done. Otherwise, there should be two indices, say 1 and 2, such that

\[
u_1^H B u_1 > \frac{B \cdot Z}{r} \quad \text{and} \quad u_2^H B u_2 < \frac{B \cdot Z}{r}.
\]

Denote \( u_1^H A u_2 = \gamma_1 e^{i \omega_1} \) and \( u_1^H B u_2 = \gamma_2 e^{i \omega_2} \). Let \( w = \gamma e^{i \alpha} \in \mathbb{C} \) with \( \alpha = \alpha_1 + \pi/2 \) and \( \gamma > 0 \) a root of the real quadratic equation in terms of \( x \):

\[
\left(u_1^H B u_1 - \frac{B \cdot Z}{r}\right) x^2 + 2(\gamma_2 \sin(\alpha_2 - \alpha_1)) x + u_2^H B u_2 - \frac{B \cdot Z}{r} = 0.
\]

(1)

Remark that since \( u_1^H B u_1 - B \cdot Z/r > 0 \) and \( u_2^H B u_2 - B \cdot Z/r < 0 \), the above equation must have two real roots with opposite signs, and \( \gamma \) is taken to be the positive root.

Set

\[
v_1 = (w u_1 + u_2)/\sqrt{1 + \gamma^2}, \quad v_2 = (-u_1 + w u_2)/\sqrt{1 + \gamma^2}.
\]

It is easy to verify that

\[
v_1 v_1^H + v_2 v_2^H = u_1 u_1^H + u_2 u_2^H.
\]

Moreover,

\[
(1 + \gamma^2) v_1^H A v_1 = (\bar{w} u_1^H + u_2^H) A (w u_1 + u_2)
\]

\[
= \gamma^2 u_1^H A u_1 + u_2^H A u_2 + \bar{w} u_1^H A u_2 + w u_1^H A u_1
\]

\[
= \gamma^2 u_1^H A u_1 + 2 \gamma \gamma_1 \text{Re} e^{i(\alpha_1 - \alpha)} + u_2^H A u_2
\]

\[
= \gamma^2 u_1^H A u_1 + u_2^H A u_2
\]

\[
= (\gamma^2 + 1) \frac{A \cdot Z}{r},
\]

which amounts to \( v_1^H A v_1 = A \cdot Z/r \). Therefore, \( v_2^H A v_2 = A \cdot Z/r \). At the same time, we have

\[
(1 + \gamma^2) v_1^H B v_1 = (\bar{w} u_1^H + u_2^H) B (w u_1 + u_2)
\]

\[
= \gamma^2 u_1^H B u_1 + u_2^H B u_2 + 2 \text{Re}(\bar{w} u_1^H B u_2)
\]

\[
= \gamma^2 u_1^H B u_1 + 2 \gamma \gamma_2 \sin(\alpha_2 - \alpha_1) + u_2^H B u_2
\]

\[
= (1 + \gamma^2) \frac{B \cdot Z}{r},
\]

where in the last equality we use the fact that \( \gamma \) solves (1).

Due to (2), by letting \( z_1 = v_1 \) we get

\[
Z - z_1 z_1^H = Z - v_1 v_1^H = \sum_{j=2}^{r} u_j u_j^H \succeq 0.
\]
We conclude that \( z_j^* A z_j = A \cdot Z / r \) and \( z_j^* B z_j = B \cdot Z / r \). Note that \( \text{rank}(Z - z_j^* z_j^H) = r - 1 \) and \( v_j^* A v_j = u_j^* A u_j = A \cdot Z / r \) for \( j = 3, \ldots, r \). Repeating this process, we obtain a rank-one decomposition for \( Z \):

\[
Z = \sum_{j=1}^r z_j z_j^H,
\]

with the property that \( z_j^* A z_j = A \cdot Z / r \) and \( z_j^* B z_j = B \cdot Z / r \), \( j = 2, \ldots, r \). \( \square \)

Remark that when we construct the new vectors \( v_1, v_2 \) by choosing \( w \in \mathbb{C} \) in the above proof, there are in fact two independent quantities: the argument and the modulus of \( w \), which makes it possible to involve two Hermitian matrices \( A \) and \( B \). Exactly for this reason this result does not hold for the real matrices.

An immediate corollary follows.

Corollary 2.1. Let \( A, B \in \mathbb{R}^n \) be two arbitrary matrices. Let \( Z \in \mathbb{R}^n \) be a positive semidefinite matrix of rank \( r \). Suppose that \( A \cdot Z \succeq_1 0 \) and \( B \cdot Z \succeq_2 0 \), where \( \succeq_1, \succeq_2 \in \{\succeq, \leq, =, >, <\} \). Then there is a rank-one decomposition for \( Z \)

\[
Z = \sum_{j=1}^r z_j z_j^H
\]

such that \( z_j^* A z_j \succeq_1 0 \) and \( z_j^* B z_j \succeq_2 0 \) for all \( j = 1, \ldots, r \).

3. Cone of complex nonnegative quadratic functions. In this section, by employing the rank-one decomposition theorem, we aim at characterizing by linear matrix inequality various matrix cones formed by complex Hermitian quadratic functions that are nonnegative over a specific domain.

Let \( D \subset \mathbb{C}^n \) be a given set. Consider all Hermitian matrices that are copositive over \( D \), i.e.,

\[
\mathcal{C}_+(D) = \{ Z \in \mathbb{R}^n : z^* Z z \geq 0, \forall z \in D \}.
\]

Clearly, \( \mathcal{C}_+(D) \) is a closed convex cone in \( \mathbb{R}^n \). The cone of all complex quadratic functions that are nonnegative over \( D \) is defined by

\[
\mathcal{F}\mathcal{C}_+(D) = \left\{ \begin{bmatrix} c & b^H \\ b & A \end{bmatrix} \in \mathbb{R}^{n+1} : c + 2 \text{Re}(b^H z) + z^H A z \geq 0, \forall z \in D \right\}.
\]

For a quadratic function \( Q(z) = z^* A z + 2 \text{Re}(b^H z) + c \), we introduce its matrix representation as

\[
Q(z) = M(Q(\cdot)) \begin{bmatrix} 1 \\ z \\ z^H \end{bmatrix},
\]

where

\[
M(Q(\cdot)) = \begin{bmatrix} c & b^H \\ b & A \end{bmatrix}.
\]

Apparently, \( Q(z) \geq 0 \) for all \( z \in D \) if and only if \( M(Q(\cdot)) \in \mathcal{F}\mathcal{C}_+(D) \). The homogenization of a given set \( D \) is defined by

\[
\mathcal{H}(D) = \text{cl}\left\{ \begin{bmatrix} s \\ z \end{bmatrix} \in \mathbb{R}_{++} \times \mathbb{C}^n : z/s \in D \right\},
\]

where \( \text{cl} \) stands for the closure operation.

For a given set \( D \) we denote by \( \text{conv}(D) \) the convex hull of \( D \), i.e., the intersection of all convex sets containing \( D \), and by \( \text{cone}(D) \) the convex cone hull of \( D \), i.e., the intersection of all convex cones containing \( D \). The dual cone of \( \mathcal{H} \) in \( \mathcal{H}^* \) is defined as \( \mathcal{H}^* = \{ Y \in \mathcal{H}^* : Y \cdot Z \geq 0, \forall Z \in \mathcal{H} \} \). Following similar arguments as in Sturm and Zhang [9], the next two propositions are immediate.

Proposition 3.1. It holds that

\[
\mathcal{C}_+(D) = (\text{cone}(z z^H : z \in D))^* = \text{cl}\text{cone}(z z^H : z \in \text{cl}\text{cone}(D)).
\]
Proposition 3.2. For any nonempty set \( D \subset \mathbb{C}^n \), there holds

\[
\mathcal{F} \mathcal{E}_\ast (D) = \mathcal{E}_\ast (\mathcal{H} (D)) = \bigcup_{u \in \mathcal{C} \mid |u| = 1} (u \mathcal{H} (D)).
\]

In what follows, we shall give a characterization of \( \mathcal{E}_\ast (D) \) where \( D \) is defined by

\[
D = \{ z \in \mathbb{C}^n : z^H A z \geq 0, z^H B z \geq 0 \}.
\]

Our next result follows directly from Theorem 2.1.

Theorem 3.1. Suppose that \( A, B \in \mathbb{K}^n \) and \( D = \{ z \in \mathbb{C}^n : z^H A z \geq 0, z^H B z \geq 0 \} \). Then, we have

\[
\text{cone} \{ z z^H : z \in D \} = \text{conv} \{ z z^H : z \in D \} = \{ Z \geq 0 : A \cdot Z \geq 0, B \cdot Z \geq 0 \}.
\]

Proof. Obviously, \( \text{conv} \{ z z^H : z \in D \} \subseteq \text{cone} \{ z z^H : z \in D \} \). The equality follows from the observation that \( \text{conv} \{ z z^H : z \in D \} \) is itself a convex cone. That \( \text{conv} \{ z z^H : z \in D \} \subseteq \{ Z \geq 0 : A \cdot Z \geq 0, B \cdot Z \geq 0 \} \) is clear, thanks to Carathéodory’s theorem. Now, \( \{ Z \geq 0 : A \cdot Z \geq 0, B \cdot Z \geq 0 \} \subseteq \text{conv} \{ z z^H : z \in D \} \) follows from Theorem 2.1 by construction. □

The dual form of Theorem 3.1 is also known as the S-Lemma, which we shall present below. The result was first shown by Fradkov and Yakubovich [4], though their proof was totally different.

Theorem 3.2. Suppose that \( A, B \in \mathbb{K}^n \) and \( D = \{ z \in \mathbb{C}^n : z^H A z \geq 0, z^H B z \geq 0 \} \). Furthermore, suppose that there is \( z_0 \in \mathbb{C}^n \) such that \( z_0^H A z_0 > 0, z_0^H B z_0 > 0 \). Then

\[
\{ Z \in \mathbb{K}^n : z^H Z z \geq 0, \forall z \in D \} = \{ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, Z - \lambda_1 A - \lambda_2 B \geq 0 \}.
\]

Proof. It follows Proposition 3.1, the bipolar theorem, and Theorem 3.1 that

\[
\mathcal{E}_\ast (D) = \{ Z : z^H Z z \geq 0, \forall z \in D \}
\]

\[
= (\text{conv} \{ z z^H : z \in D \})^*
\]

\[
= ((Z \geq 0 : A \cdot Z \geq 0, B \cdot Z \geq 0))^*
\]

\[
= \text{cl} [ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, Z - \lambda_1 A - \lambda_2 B \geq 0 ].
\]

It remains to show that \( \{ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, Z - \lambda_1 A - \lambda_2 B \geq 0 \} \) is a closed set. To this end, take any sequence \( s_k, t_k \geq 0 \) such that

\[
Z_k - s_k A - t_k B \geq 0 \quad \text{for } k = 1, 2, \ldots
\]

and \( Z_k \to Z \). Then we have

\[
z_0^H Z_k z_0 \geq s_k z_0^H A z_0 + t_k z_0^H B z_0 \geq s_k z_0^H A z_0 \geq 0,
\]

which implies that \( 0 \leq s_k \leq z_0^H Z_k z_0 / z_0^H A z_0 \) for each \( k \). That is, the sequence \( \{ s_k \} \) is bounded and hence has a cluster point, say \( s_0 \geq 0 \). In a similar way, we can prove that the subsequence \( \{ t_k \} \) has a cluster point, say \( t_0 \geq 0 \). By (5) we have

\[
Z - s_0 A - t_0 B \geq 0.
\]

That is, \( Z \in \{ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, Z - \lambda_1 A - \lambda_2 B \geq 0 \} \), and so

\[
\mathcal{E}_\ast (D) = \text{cl} [ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, Z - \lambda_1 A - \lambda_2 B \geq 0 ] = \{ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, Z - \lambda_1 A - \lambda_2 B \geq 0 \}.
\]

The desired result is proven. □

Theorem 3.2 can be further generalized. Consider \( \triangleright \in \{ \geq, \leq, =, \emptyset \} \), where \( \emptyset \) means the relation to be unrelated, and denote

\[
\triangleright^* \text{ to be }
\]

\[
\begin{cases}
\geq, & \text{if } \triangleright \text{ is } \geq; \\
\leq, & \text{if } \triangleright \text{ is } \leq; \\
\emptyset, & \text{if } \triangleright \text{ is } =; \\
=, & \text{if } \triangleright \text{ is } \emptyset.
\end{cases}
\]
Theorem 3.3. Suppose that \( A, B \in \mathcal{H}^n \). Let \( D = \{ z \in \mathbb{C}^n : z^H A z \geq 0, z^H B z \geq 0 \} \). Then

\[
\{ z \in \mathbb{R}^n : z^H Z z \geq 0, \forall z \in D \} = (\{ z \geq 0 : A \cdot Z \geq 0, B \cdot Z \geq 0 \})^* = \mathcal{H}(D).
\]

Corollary 3.1. Suppose that \( A, B \in \mathcal{H}^n \). Let \( D = \{ z \in \mathbb{C}^n : z^H A z \geq 0, z^H B z = 0 \} \). Suppose furthermore that there are \( z_1, z_2, z_3 \in \mathbb{C}^n \) such that \( z_i^H A z_i > 0, z_i^H B z_i = 0, z_2^H B z_2 > 0, \) and \( z_3^H B z_3 < 0 \). Then

\[
\{ z \in \mathbb{R}^n : z^H Z z \geq 0, \forall z \in D \} = \{ z \geq 0 : \exists \lambda_1 \geq 0, \lambda_2 \in \mathbb{R}, Z - \lambda_1 A - \lambda_2 B \geq 0 \}.
\]

Corollary 3.2. Suppose that \( A, B \in \mathcal{H}^n \). Let \( D = \{ z \in \mathbb{C}^n : z^H A z = 0, z^H B z = 0 \} \). Suppose furthermore that there are \( z_1, z_2, z_3, z_4 \in \mathbb{C}^n \) such that \( z_1^H A z_1 > 0, z_2^H B z_2 = 0, z_2^H B z_2 > 0, \) and \( z_4^H B z_4 < 0 \). Then

\[
\{ z \in \mathbb{R}^n : z^H Z z \geq 0, \forall z \in D \} = \{ z \geq 0 : \exists \lambda_1 \geq 0, \lambda_2 \in \mathbb{R}, \lambda_3 \geq 0 \}.
\]

Let us now consider nonhomogeneous quadratic functions. Suppose that

\[
D = \{ z \in \mathbb{C}^n : q_j(z) \geq 0, q_k(z) \geq 0 \},
\]

where \( q_j(z) = z^H A_j z + 2 \text{Re}(b_j^H z) + c_j, \quad j, k = 1, 2. \)

Lemma 3.1. Let \( D \) be a nonempty set as defined by (6). Then

\[
\bigcup_{u \in \mathbb{C}, |u| = 1} (u\mathcal{H}(D)) = \left\{ \begin{bmatrix} t \cr z \end{bmatrix} \in \mathbb{C}^{n+1} : \begin{bmatrix} c_j & b_j^H \\ b_j & A_j \end{bmatrix} \cdot \begin{bmatrix} |t|^2 & t z^H \\ t z & z z^H \end{bmatrix} \geq 0, \quad j = 1, 2 \right\}.
\]

Proof. That

\[
\bigcup_{u \in \mathbb{C}, |u| = 1} (u\mathcal{H}(D)) \subseteq \left\{ \begin{bmatrix} t \cr z \end{bmatrix} \in \mathbb{C}^{n+1} : \begin{bmatrix} c_j & b_j^H \\ b_j & A_j \end{bmatrix} \cdot \begin{bmatrix} |t|^2 & t z^H \\ t z & z z^H \end{bmatrix} \geq 0, \quad j = 1, 2 \right\}
\]

is readily seen by definition. We need only show the other containing relationship. Take any arbitrary

\[
\begin{bmatrix} t \cr z \end{bmatrix} \in \left\{ \begin{bmatrix} t \cr z \end{bmatrix} \in \mathbb{C}^{n+1} : \begin{bmatrix} c_j & b_j^H \\ b_j & A_j \end{bmatrix} \cdot \begin{bmatrix} |t|^2 & t z^H \\ t z & z z^H \end{bmatrix} \geq 0, \quad j = 1, 2 \right\}.
\]

If \( t \neq 0 \), then

\[
\frac{z^H}{t} A_j z + 2 \text{Re}(b_j^H z) + c_j \geq 0, \quad j = 1, 2.
\]

That is, \( z/t \in D \). Let \( t = \gamma e^{i\alpha} \). Then \( \gamma z^T e^{i\alpha} = \gamma z \) \( \in \mathcal{H}(D) \), which means \( \gamma e^{i\alpha} z^T e^{i\alpha} = e^{i\alpha}(\mathcal{H}(D)) \), implying that \( [t \ z]^T \in \mathcal{H}(D) \). If \( t = 0 \), then (7) implies that \( z^H A_j z \geq 0 \) for \( j = 1, 2 \). In that case, if \( z = 0 \) then \( [0 \ 0]^T = [t \ z]^T \in \mathcal{H}(D) \), since \( \mathcal{H}(D) \) is a closed cone.

Now we consider the case where \( z \neq 0 \). Let \( z_0 \in D \), i.e., \( q_j(z_0) \geq 0 \) for \( j = 1, 2 \). For a given nonzero \( \epsilon \in \mathbb{C} \), we consider

\[
q_j(z_0 + \epsilon z) = |\epsilon|^2 z_0^H A_j z + 2 \text{Re}(A_j z_0 + b_j^H z) + q_j(z_0), \quad j = 1, 2.
\]

In order to show that \( \{ 0 \ z^T \} \in \bigcup_{u \in \mathbb{C}, |u| = 1} (u\mathcal{H}(D)) \), we discuss the following four cases:

Case 1. \( \text{Re}(A_j z_0 + b_j^H z) \geq 0 \) for \( j = 1, 2 \). It follows that \( q_j(z_0 + \epsilon z) \geq 0 \) for \( j = 1, 2 \), i.e., \( z_0 + \epsilon z \in D \). Let \( \epsilon = |\epsilon| e^{i\alpha} \). Then

\[
\begin{align*}
z_0 + \epsilon z & = \frac{1/|\epsilon| z_0 + z e^{i\alpha}}{1/|\epsilon|} \\
& \in \mathcal{H}(D) \\
& \Rightarrow \begin{bmatrix} 1/|\epsilon| \\
1/|\epsilon| z_0 + z e^{i\alpha} \end{bmatrix} \in \mathcal{H}(D) \\
& \Rightarrow \begin{bmatrix} 0 \\
z e^{i\alpha} \end{bmatrix} \in \mathcal{H}(D) \\
& \Rightarrow \begin{bmatrix} 0 \\
z \end{bmatrix} \in e^{-i\alpha} \mathcal{H}(D) \subseteq \bigcup_{u \in \mathbb{C}, |u| = 1} (u\mathcal{H}(D)).
\end{align*}
\]
Case 2. \( \text{Re}(e(A, z_0 + b)^H z) \leq 0 \) for \( j = 1, 2 \). Replacing \( \epsilon \) by \(-\epsilon\), this reduces to the previous case.

Case 3. \( \text{Re}(e(A, z_0 + b)^H z) < 0 \) and \( \text{Re}(e(A, z_0 + b)^H z) > 0 \). Let \( (A, z_0 + b)^H z = \gamma_j e^{i\theta_j} \) for \( j = 1, 2 \). Then in this case we have \( \text{Re}(e(\alpha + \beta_1) z) < 0 \) and \( \text{Re}(e(\alpha + \beta_2) z) > 0 \), i.e., \( \text{Re}(e(\alpha + \beta_1) < 0 \) and \( \text{Re}(e(\alpha + \beta_2) > 0 \).

By rotating \( e^{i(\alpha + \beta_1)} \) and \( e^{i(\alpha + \beta_2)} \) simultaneously, it follows that there is \( \Delta \alpha \) such that \( \text{Re}(e^{i(\alpha + \Delta) z}) \geq 0 \) and \( \text{Re}(e^{i(\alpha + \Delta + \beta_2) z}) \geq 0 \). Therefore we have \( \text{Re}(e(\gamma_j e^{i(\alpha + \Delta + \beta_2) z}) \geq 0 \) and \( \text{Re}(e(\gamma_j e^{i(\alpha + \Delta + \beta_1) z}) \geq 0 \). This implies that \( q_j(z_0 + \epsilon e^{i(\alpha + \Delta) z}) \geq 0 \), \( j = 1, 2 \), i.e., \( z_0 + \epsilon e^{i(\alpha + \Delta) z} \in D \). Then using a similar argument as in Case 1, we conclude that

\[
\begin{bmatrix}
0 \\
\vdots \\
0
\end{bmatrix}
\in (e^{i(\alpha + \Delta) z}) (D) \subseteq \bigcup_{u \in C, |u| = 1} (u \mathbb{H}(D)).
\]

Case 4. \( \text{Re}(e(A, z_0 + b)^H z) > 0 \) and \( \text{Re}(e(A, z_0 + b)^H z) < 0 \). Replacing \( \epsilon \) by \(-\epsilon\), this is the same as Case 3. The proof is thus complete. \( \square \)

We remark that Lemma 3.1 is an extension of Sturm and Zhang [9, Lemma 2], where \( D \) is defined by only one real quadratic function.

**Theorem 3.4.** Let \( D = \{ z \in C^n : q_j(z) = z^H A_j z + 2 \text{Re}(b_j^H z) + c_j \geq 0, \ j = 1, 2 \} \) be nonempty. Suppose that there is \( z_0 \in C^n \) such that \( q_j(z_0) > 0 \) and \( q_j(z_0) > 0 \). Then

\[
\mathcal{F}_+ C(D) = \{ Z : \exists \lambda_1 \geq 0, \lambda_2 \geq 0 \text{ such that } Z - \lambda_1 M(q_1(z)) - \lambda_2 M(q_2(z)) \geq 0 \}.
\]

**Proof.** It follows that

\[
\mathcal{F}_+ C(D) = \mathcal{C}_+ \left( \bigcup_{u \in C, |u| = 1} (u \mathbb{H}(D)) \right) \quad \text{(Proposition 3.2)}
\]

\[
= \left( \text{cone} \left( \begin{bmatrix} I & I \end{bmatrix}, \begin{bmatrix} I & I \end{bmatrix} \in \bigcup_{u \in C, |u| = 1} (u \mathbb{H}(D)) \right) \right)^* \quad \text{(Proposition 3.1)}
\]

\[
= \left( \text{conv} \left( \begin{bmatrix} I & I \end{bmatrix}, \begin{bmatrix} I & I \end{bmatrix} \in \bigcup_{u \in C, |u| = 1} (u \mathbb{H}(D)) \right) \right)^* \quad \text{(Theorem 3.1)}
\]

\[
= \left( \text{conv} \left( \begin{bmatrix} I & I \end{bmatrix}, \begin{bmatrix} I & I \end{bmatrix} \in \bigcup_{u \in C, |u| = 1} (u \mathbb{H}(D)) \right) \right)^* \quad \text{(Lemma 3.1)}
\]

\[
= \left( \{ Z \in C_n^+ : M(q_1(z)) \cdot Z \geq 0, \ j = 1, 2 \} \right)^*
\]

\[
= \text{cl} \{ Z \in C_n^+ : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, \ Z - \lambda_1 M(q_1(z)) - \lambda_2 M(q_2(z)) \geq 0 \}
\]

\[
= \{ Z \in C_n^+ : \exists \lambda_1 \geq 0, \lambda_2 \geq 0, \ Z - \lambda_1 M(q_1(z)) - \lambda_2 M(q_2(z)) \geq 0 \}. \quad \square
\]

We remark that Theorem 3.4 can be regarded as a generalization of Sturm and Zhang [9, Corollary 5]. Note that from Proposition 3.2 we have \( \mathcal{F}_+ C(C^n) = C_n^+ \). Then Theorem 3.4 implies that whenever \( D = \{ z : q_j(z) \geq 0, \ j = 1, 2 \} \) has a strict interior point, then \( q_j(z) \geq 0 \) for all \( z \in D \) if and only if there are \( \lambda_1, \lambda_2 \geq 0 \) such that \( q_j(z) - \lambda_1 q_1(z) - \lambda_2 q_2(z) \geq 0 \) for \( z \in C^n \).

**4. Complex quadratic programming and SDP relaxation.** Consider the complex quadratically constrained quadratic programming:

\[
\text{(QCQP)} \quad \max \ z^H Qz + 2 \text{Re} z^H q
\]

\[
s.t. \ z^H A_j z + 2 \text{Re} z^H b_j + c_j \leq 0, \ j = 1, \ldots, m,
\]

where \( Q, A_j \in C^n, b_j, q \in C^n, c_j \in \mathbb{R}, j = 1, \ldots, m. \) Denote

\[
B_0 = \begin{bmatrix} 0 & Q^H \\ Q & 0 \end{bmatrix}, \quad B_j = \begin{bmatrix} c_j & b_j^H \\ b_j & A_j \end{bmatrix}, \quad j = 1, \ldots, m, \quad B_{m+1} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.
\]

We rewrite (QCQP) equivalently as

\[
\text{(QCQP)} \quad \max \ B_0 \cdot \begin{bmatrix} 1 \\ z \\ z^H \end{bmatrix}
\]

\[
s.t. \ B_j \cdot \begin{bmatrix} 1 \\ z \\ z^H \end{bmatrix} \leq 0, \quad j = 1, \ldots, m.
\]
A homogenized version of (QCQP) is
\[
\begin{aligned}
\text{(HQ) } \quad & \max \ B_0 \cdot \begin{bmatrix} \vert t \vert^2 & t z^H \\ \bar{t} z & z z^H \end{bmatrix} \\
\text{s.t. } & \quad B_j \cdot \begin{bmatrix} \vert t \vert^2 & t z^H \\ \bar{t} z & z z^H \end{bmatrix} \leq 0, \quad j = 1, \ldots, m, \\
& \quad B_{m+1} \cdot \begin{bmatrix} \vert t \vert^2 & t z^H \\ \bar{t} z & z z^H \end{bmatrix} = 1.
\end{aligned}
\]

It follows that if \([t \ z^T]^T\) solves (HQ), then \(z/t\) solves (QCQP). The SDP relaxation of (QCQP) is
\[
\begin{aligned}
\text{(QCQPR) } \quad & \max \ B_0 \cdot Z \\
\text{s.t. } & \quad B_j \cdot Z \leq 0, \quad j = 1, \ldots, m, \\
& \quad B_{m+1} \cdot Z = 1, \\
& \quad Z \succeq 0,
\end{aligned}
\]
with the dual given by
\[
\begin{aligned}
\text{(DQCQPR) } \quad & \min \ y_0 \\
\text{s.t. } & \quad Y = \sum_{j=1}^m y_j B_j - B_0 + y_0 B_{m+1} \succeq 0, \\
& \quad y_j \geq 0, \quad j = 1, \ldots, m, \quad y_0 \text{ free}.
\end{aligned}
\]

Throughout this section, we assume that (QCQP) satisfies the Slater condition, i.e., there exists \(z_0 \in \mathbb{C}^n\) such that \(q_j(z_0) < 0, \quad j = 1, \ldots, m\). Accordingly, (QCQPR) satisfies the Slater condition as well.

It is well known that (QCQP) is NP-hard in general. In the remainder of this section, we shall study (QCQP) where \(m\) is small.

**Theorem 4.1.** Suppose that (QCQPR) and (DQCQPR) have complementary optimal solutions. Moreover, suppose that \(m = 2\). Then (QCQP) and (QCQPR) have the same optimal value. Moreover, an optimal solution for (QCQP) can be constructed from an optimal solution for (QCQPR) in polynomial time.

**Proof.** Let \(Z^* \succeq 0\) be an optimal solution of (QCQPR), and \((y_0^*, y_1^*, y_2^*, Y^*)\) be an optimal solution of (DQCQPR). Since the strong duality is satisfied, the respective primal and dual optimal solutions are complementary, i.e., \(Z^* \cdot Y^* = 0\).

Denote “\(\leq\)” to be either “\(<\)” or “\(=\)”. Then \(B_j \cdot Z^* \leq 0, \quad j = 1, 2\). By Theorem 2.1 (or Corollary 2.1), there exist nonzero \(z_k, \quad k = 1, \ldots, r\), where \(r\) is the rank of \(Z^*\) such that
\[
Z^* = \sum_{k=1}^r \bar{z}_k z_k^H, \quad B_j \cdot \bar{z}_k z_k^H \leq 0, \quad j = 1, 2, \quad k = 1, \ldots, r.
\]

Since \(Z^*_{11} = 1\), there is \(l \in \{1, \ldots, r\}\) such that \(t_l \neq 0\) where \(z_l = [t_l \ z^T_l]^T\). Therefore, \(q_j(\bar{z}_l/t_l) \leq 0, \quad j = 1, 2\), which implies that \(\bar{z}_l/t_l\) is a feasible solution for (QCQP).

Due to \(Y^* \succeq 0\), we have \(Y^* \cdot \bar{z}_l z_l^H = 0\). If \(B_j \cdot Z^* < 0\), then by complementarity it follows that \(y_j^* = 0\). If \(B_j \cdot Z^* = 0\), then by the decomposition theorem we have \(B_j \cdot \bar{z}_l z_l^H = 0\). Therefore, we always have \(y_j^* (B_j \cdot \bar{z}_l z_l^H) = 0, \quad j = 1, 2\). This, combining with \(Y^* \cdot \bar{z}_l z_l^H = 0\), leads to the conclusion that \([1 \ z_l^T/t_l]^T [1 \ z_l^T/t_l] \cdot \bar{z}_l z_l^H = 0\) is a solution of (QCQPR). Therefore \(\bar{z}_l/t_l\) is optimal for (QCQP). Note that the rank-one decomposition procedure runs in polynomial time. The theorem is proven. \(\square\)

We remark that Theorem 4.1 is an extension of Ye and Zhang [11, Theorem 2.3]. Note further that we do not have to assume a nonbinding condition in Theorem 4.1, which however is necessary in Ye and Zhang [11].

Not all SDP problems are relaxations of quadratic programs. In the next section, we shall study the rank of optimal solutions for a general complex SDP problem.
5. The low rank optimal solutions for standard complex SDP. Consider a standard (complex) SDP problem

\[
\begin{align*}
\text{(SDP)} \quad \min & \quad C \cdot Z \\
\text{s.t.} & \quad A_j \cdot Z = b_j, \quad j = 1, \ldots, m, \\
& \quad Z \succeq 0,
\end{align*}
\]

and its dual

\[
\begin{align*}
\text{(DSDP)} \quad \max & \quad \sum_{j=1}^{m} y_j b_j \\
\text{s.t.} & \quad \sum_{j=1}^{m} y_j A_j \preceq C.
\end{align*}
\]

Suppose that (SDP) and (DSDP) have a complementary optimal solution pair. Consider now an optimal solution for (SDP) with minimum rank. In particular, let \( S_P \) be the set of all optimal solutions for (SDP), introduce

\[ r_P = \min \{ \text{rank}(Z) : Z \in S_P \}, \]

and let \( Z^* \) be such an optimal solution with rank \( \text{rank}(Z^*) = r_P \).

For this given \( Z^* \), let us introduce the following notion of minimum diagonal rank:

\[ r_M = \min \{ \text{rank}(\text{diag}(V^H A_1 V), \ldots, \text{diag}(V^H A_m V)) : VV^H = Z^*, \text{rank}(V) = \text{rank}(Z^*) = r_P \}. \tag{8} \]

The result below follows from Theorem 2.1.

**Proposition 5.1.** Suppose that \( S_P \neq \emptyset \) and \( m \geq 3 \). We have \( r_M \leq m - 2 \).

**Proof.** Consider the case that at least three of the values \( \{b_1, b_2, \ldots, b_m\} \) are nonzero. (In the other case, namely at most two of the \( b_j \)'s are nonzero, the proof can be easily adapted.) Without losing generality, let us assume that \( b_1 \), \( b_2 \), and \( b_3 \) are nonzero.

Take any \( Z \in S_P \) with rank \( r \). Since

\[ (A_1/b_1 - A_2/b_2) \cdot Z = 0 \quad \text{and} \quad (A_1/b_1 - A_3/b_3) \cdot Z = 0, \]

Theorem 2.1 asserts that there is a rank-one decomposition of \( Z \),

\[ Z = \sum_{k=1}^{r} v_k v_k^H, \]

such that

\[ v_k^H (A_1/b_1 - A_2/b_2) v_k = 0, \quad \text{and} \quad v_k^H (A_1/b_1 - A_3/b_3) v_k = 0 \]

for all \( k = 1, \ldots, r \). Letting \( V = [v_1, \ldots, v_r] \), we thus have

\[ \text{diag}(V^H A_1 V)/b_1 = \text{diag}(V^H A_2 V)/b_2 = \text{diag}(V^H A_3 V)/b_3. \]

Hence,

\[ \text{rank}(\text{diag}(V^H A_1 V), \ldots, \text{diag}(V^H A_m V)) \leq m - 2. \]

The proposition is proven. □

Let us denote \( d_D \) to be the dimension of the optimal solution set for (DSDP). Theorem 5.1 gives an upper bound on the lowest rank among all the optimal solutions.

**Theorem 5.1.** Suppose that the complex SDP pair (SDP) and (DSDP) have a complementary optimal solution pair, and \( m \geq 3 \). Then, it holds that

\[ r_P \leq \min \{ r_M, \lfloor \sqrt{m - d_D} \rfloor \}. \]
Proof. For $Z^* \in S_p$ with $\text{rank}(Z^*) = r_p$, let $Z^* = VV^H$ be the decomposition attaining the minimum diagonal rank as defined in (8). Consider the following system of linear equations:

$$(\text{diag}(V^HA_1V))^T x = A_1 \cdot \left( \sum_{k=1}^{r_p} x_k v_k v_k^H \right) = 0$$

$$(\text{diag}(V^HA_2V))^T x = A_2 \cdot \left( \sum_{k=1}^{r_p} x_k v_k v_k^H \right) = 0$$

$$\vdots$$

$$(\text{diag}(V^HA_mV))^T x = A_m \cdot \left( \sum_{k=1}^{r_p} x_k v_k v_k^H \right) = 0.$$ 

The rank of the coefficient matrix of the above linear equation is $r_P$ and the number of (real) variables is $r_P$ ($x \in \mathbb{R}^{r_P}$). If $r_P > r_M$, then the above equation must have a nonzero solution $x \in \mathbb{R}^{r_P}$ with $x \not= 0$. In that case, it would follow that

$$Z^*(i) = \sum_{k=1}^{r_p} (1-tx_k) v_k v_k^H$$

is also an optimal solution for (SDP) for all $t \leq \hat{t} := \min\{1/x_k: \ x_k > 0, k = 1, \ldots, r_p\}$. In particular, $\text{rank}(Z^*(\hat{t})) \leq r_p - 1$, contradicting the fact that $Z^*$ is the minimum rank optimal solution. This shows that $r_p \leq r_M$.

We do not necessarily restrict the directions to be diagonal. As an alternative, consider the equation

$$(V^HA_1V) \cdot \Delta = 0$$

$$(V^HA_2V) \cdot \Delta = 0$$

$$\vdots$$

$$(V^HA_mV) \cdot \Delta = 0$$

(9)

where $\Delta \in \mathcal{H}^{r_p}$.

Due to the complementarity, we have

$$\left( C - \sum_{j=1}^{m} y_j A_j \right) VV^H = 0$$

for any dual optimal solution $(y_1, \ldots, y_m)$. Thus, by the positive semidefiniteness of the matrices, we have

$$V^H CV - \sum_{j=1}^{m} y_j V^H A_j V = 0.$$ 

Therefore, the rank of the coefficient matrix in (9) is $m - d_P$. Since the dimension of $\Delta$ is $r_P^2$, this implies that as long as $r_P^2 > m - d_P$, Equation (9) would admit a nonzero solution $\Delta \in \mathcal{H}^{r_P}$, allowing $V(\hat{I} - t\Delta)V^H$ to be optimal for (SDP) with $t$ satisfying $t\Delta \preceq I$, thereby enabling a possibility to further reduce the rank of $Z^*$. Again, this contradicts the fact that $Z^*$ has minimum rank among optimal solutions. This in turn shows that we must have $r_P^2 \leq m - d_P$. Since $r_P$ is integer, we thus have $r_P \leq \lfloor \sqrt{m - d_P} \rfloor$. The theorem is proven. □

Note that since the diagonal of a matrix is only a part of the whole matrix, naturally we have $r_M \leq m - d_P$. In general, we may expect $r_M$ to be much less than $m - d_P$ indeed.

As a consequence of Theorem 5.1, we conclude that (SDP) has a rank-one optimal solution if $m \leq 3$, since in this case it follows from Proposition 5.1 and Theorem 5.1 that $r_p \leq \min\{3 - 2, \lfloor \sqrt{3} - 0 \rfloor\} = 1$. Hence Theorem 5.1 generalizes a result in Ye and Zhang [11, §2.2].

It also follows from Theorem 5.1 that if $m = 4$ and the dual optimal solution is not unique ($d_P \geq 1$), then there is a rank-one optimal solution for (SDP).

Remark that in the real case the discussion on the minimum rank optimal solutions for SDP can be found in Barvinok [2], Pataki [6], Ye and Zhang [11], and Ye [10].
6. Joint numerical range and matrix decomposition. Let $A_j \in \mathcal{H}^n$ for $j = 1, \ldots, m$ be Hermitian matrices, and $D \in \mathcal{H}_+^n$ be a Hermitian positive definite matrix. The joint numerical range of this family $\{A_1, \ldots, A_m, D\}$ of Hermitian matrices is defined as

$$\mathcal{F}(A_1, \ldots, A_m; D) := \left\{ \begin{pmatrix} A_1 \cdot z^H \\ \vdots \\ A_m \cdot z^H \end{pmatrix} : D \cdot z^H = 1, \ z \in \mathbb{C}^m \right\}.$$ 

To proceed, let us introduce the following set:

$$\mathcal{M}(A_1, \ldots, A_m; D) := \left\{ \begin{pmatrix} A_1 \cdot Z \\ \vdots \\ A_m \cdot Z \end{pmatrix} : D \cdot Z = 1, \ Z \in \mathcal{H}_+^n \right\}.$$ 

Furthermore, we define the set

$$\mathcal{F}(A_1, \ldots, A_m) := \left\{ \begin{pmatrix} A_1 \cdot z^H \\ \vdots \\ A_m \cdot z^H \end{pmatrix} : z \in \mathbb{C}^m \right\},$$

and similarly the set $\mathcal{M}(A_1, \ldots, A_m)$.

It is elementary to check that $\mathcal{M}(A_1, \ldots, A_m; D)$ is the convex hull of $\mathcal{F}(A_1, \ldots, A_m; D)$, hence convex. Moreover, $\mathcal{F}(A_1, \ldots, A_m)$ and $\mathcal{M}(A_1, \ldots, A_m)$ are cones, and so $\mathcal{M}(A_1, \ldots, A_m)$ is in fact a convex cone in $\mathcal{H}_+^m$.

We shall see below that a certain rank restriction on $Z$ in fact does not affect the numerical range $\mathcal{M}(A_1, \ldots, A_m; D)$, by applying the decomposition theorem discussed in §2.

**Proposition 6.1.** Let $\{A_1, \ldots, A_m; D\}$ be Hermitian matrices with $D > 0$. Suppose that $m \geq 2$. It holds that

$$\mathcal{M}(A_1, \ldots, A_m; D) := \left\{ \begin{pmatrix} A_1 \cdot Z \\ \vdots \\ A_m \cdot Z \end{pmatrix} : D \cdot Z = 1, \ Z \in \mathcal{H}_+^n, \ \text{rank}(Z) \leq m-1 \right\}.$$ 

**Proof.** Take an arbitrary $v \in \mathcal{M}(A_1, \ldots, A_m; D)$. Let $Z \in \mathcal{H}_+^n$ be such that

$$A_i \cdot Z = v_i, \ i = 1, \ldots, m, \ \ D \cdot Z = 1.$$ 

Obviously, we have

$$(A_{m-1} - v_{m-1} D) \cdot Z = 0, \ \text{and} \ (A_m - v_m D) \cdot Z = 0.$$ 

According to Theorem 2.1, there is a particular rank-one decomposition of $Z$, say $Z = \sum_{j=1}^r z_j z_j^H$ with $r = \text{rank}(Z)$, such that

$$(A_{m-1} - v_{m-1} D) \cdot z_j z_j^H = 0, \ (A_m - v_m D) \cdot z_j z_j^H = 0, \ j = 1, \ldots, r.$$ 

Let us define an $(m-1) \times r$ matrix $B = (b_{ij})$ with entries given by

$$b_{ij} := (A_i - v_i D) \cdot z_j z_j^H, \quad i = 1, \ldots, m-2, \quad j = 1, \ldots, r,$$

and consider the following equation:

$$Bt = e_{m-1}, \quad t \geq 0,$$ 

where $e_{m-1}$ is the $(m-1)$-dimensional unit vector whose last component is 1 and 0 elsewhere. Clearly, by the construction of the matrix $B$, we have $Be = e_{m-1}$ with $e$ being the vector of all ones. Therefore, there must exist some $\hat{t} \geq 0$ satisfying (10) such that the number of its components does not exceed $m-1$, which is the number of rows in $B$. Let

$$\hat{Z} = \sum_{j=1}^r \hat{t}_j z_j z_j^H.$$ 

Hence we have

$$D \cdot \hat{Z} = 1, \quad v = (A_1 \cdot \hat{Z}, \ldots, A_{m-1} \cdot \hat{Z}, A_m \cdot \hat{Z})^T, \quad \text{and} \quad \text{rank}(\hat{Z}) \leq m-1.$$ 

This completes the proof. □
By the same argument, one has the following:

**Proposition 6.2.** Let \( \{A_1, \ldots, A_m\} \) be Hermitian matrices, and \( m \geq 3 \). It holds that

\[
\mathcal{M}(A_1, \ldots, A_m) := \left\{ \begin{pmatrix} A_1 \cdot Z \\ \vdots \\ A_m \cdot Z \end{pmatrix} : Z \in \mathbb{H}^n_+, \text{rank}(Z) \leq m - 2 \right\}.
\]

Interestingly, Proposition 6.1 implies that \( \mathcal{M}(A_1, A_2; D) = \mathcal{F}(A_1, A_2; D) \), or equivalently that the set

\[
\left\{ \begin{pmatrix} z^H A_1 z \\ z^H A_2 z \\ \vdots \\ z^H A_m z \end{pmatrix} : z \in \mathbb{C}^n \right\}
\]

is convex. The last statement is a well-known result of Hausdorff [5].

Similarly, a consequence of Proposition 6.2 \( (m = 3) \) is that \( \mathcal{M}(A_1, A_2, A_3) = \mathcal{F}(A_1, A_2, A_3) \), and so

\[
\left\{ \begin{pmatrix} z^H A_1 z \\ z^H A_2 z \\ z^H A_3 z \end{pmatrix} : z \in \mathbb{C}^n \right\}
\]

is a convex cone in \( \mathbb{H}^3 \), which was first established by Brickman [3]. Furthermore, Polyak [8] was able to characterize when this cone is pointed, under an additional condition that \( n \geq 3 \).

**Acknowledgments.** The authors thank two anonymous referees for their constructive comments that helped to improve the paper. Especially, they would like to thank Jong-Shi Pang for sharing his insights on joint numerical ranges. Sections 4 and 6 used some material from an unpublished manuscript written by Jong-Shi Pang and the second author of this paper.
